Abstract. This article reviewed the effect of four parenting styles (i.e., authoritative, authoritarian, permissive, and rejecting/neglectful parenting) on self-esteem and psychological outcomes in adolescents, such as well-being, life satisfaction, and school performance. It was found that parenting styles directly impact psychological outcomes. More specifically, a positive parenting style increases the life satisfaction and well-being of young adults. The results of this review also indicate the negative side of inappropriate parenting style, which increases adolescents' aggression. Aggression is a serious problem for adolescents, which normally leads them to be involved in criminal activities. Aggression might also cause mental health problems. Parents who are irresponsible are likely to increase the tendency of aggression in adolescents. Non-aggressive adolescents showed higher self-esteem than aggressive adolescents. Furthermore, the article also reviewed the relationship among self-esteem, parenting styles, and learning. Self-esteem serves as a mediator between parenting style and learning. The level of self-esteem increased by a positive parenting style can indirectly impact school performance, such as academic procrastination and self-regulated learning. A high level of self-esteem can decrease academic problems, and it also can facilitate the development of self-confidence, which is positively correlated with academic performance. However, previous studies did not investigate differences of this relationship in boys and girls. Future research should focus more on gender differences. This review can provide some guidance for the family education programs at school and relevant intervention studies.

Keywords: Parenting style; Self-esteem; Adolescence.

1. Introduction

The relationship between parent and child is a popular topic in psychology. Psychologists divided parenting styles into four different types which are authoritative, authoritarian, permissive, and rejecting/neglectful. Parents with an authoritative parenting style tend to display high control and warmth toward children. Authoritative parents tend to be supportive and responsible guides for their children. Authoritarian parenting style refers to a parenting approach that is high in control and low in warmth. The parents are eager to control everything for their children without warm concerns. Permissive parenting indicates a decrease in control and an increase in warmth. Permissive parents usually do not control or regulate their children. Rejecting or neglectful parenting refers to low on both control and warmth. The parents are irresponsible to their children and are usually absent from their development. Parenting style impacts children in various ways. More specifically, children's relationship with their parents can impact their grades and performance in school. Depending on a previous review, Sepra states that parents with an authoritative parenting style are likely to improve their children's school performance because they always give their children enough emotional security and explanations of their boundaries. Furthermore, children can be benefited from developing an optimistic personality [1]. Children with optimistic personalities can form healthy relationships with their classmates or teachers. Parents with an authoritarian parenting style tend to restrain their children's school performance. Because authoritarian parents are always inclined to be extremely strict with their children and may cause children to lose interest in studying. A permissive parenting style also negatively impacts children's achievement. These parents have a lower expectation for their children's performance. Parents' low expectations can lead the children to have lower requirements for themselves [1]. In short, parents are essential for children's development. Their behaviors would impact children's future life.
Self-esteem indicates how people value themselves. Different levels of self-esteem can lead to different outcomes of children’s development, especially on personality. A high level of self-esteem usually enhances adolescents’ development by improving self-confidence and self-worth. It also demonstrated a positive influence on mental health. According to a previous study, Moksnes and his colleagues state that increases in self-esteem predicted a significant decrease in depression and anxiety [2]. Individuals with high self-esteem exhibited an optimistic attitude to life and a solid ability to cope with pressure. Conversely, adolescents with insufficient self-esteem are probably exposed to pressure and anxiety more. These individuals struggle to cope with life and work stress which may lead to mental health problems. However, overmuch self-esteem also might lead to a negative consequence that causes children to evolve into selfish or arrogant personalities. Thus, both overmuch and insufficient self-esteem negatively affects people, especially young adults. The primary topic of this article is to review the effect of different parenting styles on self-esteem and psychological outcomes during adolescence. Parenting style and self-esteem are two major topics in children's development areas and most studies examined these two factors separately. This paper reviewed how parenting style and self-esteem impact each other and how these two variables impact children's development together. It can provide some suggestions to future intervention studies and relevant practices regarding family education.

2. The Effects of Parenting Style on Self-Esteem and Psychological Outcomes

2.1 Parenting Style, Self-Esteem, and Identify Development

Self-esteem is an essential factor in the development of adolescents. Different styles of parenting impact children's self-esteem in various ways. According to the study by Aremu and his colleagues, authoritative parenting styles positively influenced children's self-esteem. The authoritarian, permissive, and neglectful parenting styles negatively affected children's self-esteem [3]. The authoritative parenting style is the only one that shows a positive association with self-esteem because children feel the warmth from their parents. Authoritative parents are more willing to guide children with a positive attitude. For example, they are generous in praising their children. Praising always increases self-confidence. When children make mistakes, authoritative parents talk about the reason and solution of the mistake with their children kindly rather than harshly criticizing on them. Thus, children with authoritative parents tend to present high self-esteem. Authoritarian parents often exhibit a higher level of requirements but a lower level of responsiveness to children. Children typically feel a high level of negative attitude from authoritarian parents. When children make mistakes, authoritarian parents use sharp criticism instead of reasoning with children. Criticism efficiently decreases people's confidence. A parent with a permissive style demonstrates less requirement and more warmth. Adolescents with permissive parents have extremely high self-esteem. This type of child typically lacks politeness and respect for others. Because of their self-centered personalities, children under a permissive parenting style usually find it hard to make friends. Insufficient friendship and negative relationships with other can lead to a decrease in self-esteem. Children cannot feel any love from neglectful parents. Children received neglectful parenting usually have a lower level of self-esteem.

Psychological well-being is an important standard and measurement in children’s development. It stands for happiness and health on a psychological level. Hope and self-esteem are two important aspects contained in psychological well-being. Adolescents with higher levels of hope and self-esteem are associated with a positive psychological adjustment. In contrast, adolescents with a lower level of hope and self-esteem tend to have high anxiety, depression, and a high chance of suicide. Regardless, psychological well-being is affected by parenting styles. Sashimi and his colleague conducted a four-year longitude study and declared that among self-esteem, hope, and authoritative parenting style, there is a positive association. There is a negative association among self-esteem, hope, and authoritarian parenting style. Compared to authoritative style, the permissive parenting style is related to decreases in hope and increases in psychoticism [4]. Adolescents with an
authoritative parenting style can perceive love from their parents. Love increases their self-esteem and hope. They tend to believe the future is full of happiness. Moreover, the authoritative parents offered not only love but also clear rules for children. Thus, this type of child also has a low risk to involve in antisocial problems. A high level of hope and self-esteem can lead to a less chance of involvement in dangerous activities. Children from authoritarian families lack love and support from their parents, which results in losing hope and self-esteem. Children are usually attached to the negative side of life, such as pessimistic emotions. Authoritarian parents are unwilling or impatient to guide their children. Children with permissive parents also tend to have mental health problems. They do not think about consequences while making decisions, because no one told them the consequences. They get everything they want from their parents without any requirements. Therefore, these children are easily involved in risky social activities because they think they can do anything. Also, they are hard to satisfy. If individuals are not satisfied, their well-being cannot be improved.

Life satisfaction means the overall measure regarding people's desires and actual attainment. It also is a significant aspect in children's development. Pérez-Fuente et al. state that a high level of life satisfaction is associated with higher happiness, self-esteem, and the experience of more positive sides of society. Parenting styles are an essential element that impacts life satisfaction. Parenting with a significant practice of effect and communication, better self-disclosure in their relations, low psychological control, and a high sense of humor is positively related to life satisfaction [5]. Self-esteem is the mediator between life satisfaction and parenting style. An adolescent with high self-esteem usually shows a high level of life satisfaction. Adolescents with an authoritative parenting style acquire affection and communication from their parents. A healthy relationship with family can increase children's life satisfaction. The authoritative parenting style is associated with adequate self-esteem and an optimistic personality. An optimistic personality helps children conquer difficulties in life. Conquering difficulties can reduce negative emotions and increase life satisfaction. In contrast, children with an authoritarian and neglecting parenting style showed less life satisfaction compared to authoritative style, because they have a lower level of self-esteem. The intimacy with a family member is absent and can lead to a decrease in satisfaction. The permissive style is also related to positive life satisfaction because it gives children a high level of love and support. Finally, developing self-esteem and positive emotion is essential to increase life satisfaction. Therefore, great satisfaction is associated with high love, happiness, and self-esteem.

2.2 Parenting Style, Aggression, and Self-Esteem

Aggression is a significant health issue for adolescents. Aggressive individuals usually show violent behaviors toward others. Aggressive young adults are generally difficult to blend into society. They possess fewer friends and are often involved in criminal activities. Aggressive adolescents also show a lower level of self-esteem than typically developing individuals. Parenting styles can have a strong influence on the aggression of adolescents. Perez-Gramaje and his colleagues indicate that aggressive and typically developing adolescents both showed the highest scores on self-esteem only in warm families (indulgent and authoritative). In contrast, nonaggressive teenagers indicated higher self-esteem than aggressive teenagers in authoritarian and neglecting families [6]. Authoritative and indulgent parents showed more patience and warmth to their children. Aggressive adolescents need more concern and warmth. Authoritative and indulgent parents are inclined to spend time with them. Aggressive adolescents usually show lower self-esteem than non-aggressive adolescents. However, in an authoritative family, parents use love to help adolescents improve their self-esteem. Parents from authoritarian and neglecting families lack warmth and patience. They also are not willing to spend time with their children. Some parents even ignore the problem. They are even unaware of how serious the problem is because these parents may be aggressive themselves as well. They may think aggression is normal behavior. If parents are not aware of the seriousness of the problem, children are difficult to improve. Therefore, aggressiveness needs to be treated with love and patience from parents.
3. The Mediating Role of Self-Esteem in The Relationship between Parenting Style and Learning

School performance stands as an influential factor in measuring adolescents’ learning ability. It is usually indicated by a grade. School performance is impacted by other people such as parents, teachers, and classmates. Regardless, parents is a significant influence of students’ school performance. The study habitat is always formed in early childhood. Parents have a huge responsibility toward children’s habitation formation. As mentioned above, different parenting styles have different influences on school performance. More detailed, self-esteem is a mediator between parenting style and school performance. A previous study stated that the authoritative parenting style is the possible style to improve school performance because it can lead to a high level of self-esteem for children. A high-level of self-esteem develops a high level of self-confidence and self-trust which helps students succeed in academics. For instance, a student with a high level of confidence can easily earn a positive impression of the teacher by answering questions in class and asking professional questions during office hours. It is also rare for them to have test or presentation anxiety. They are always very confident about their ability and performance. In distinction, lower self-esteem is triggered by permissive, authoritarian, and neglecting parenting, which resulted in a lower level of self-confidence and self-trust. These children tend to be nervous in lectures and communication because they are afraid of making mistakes. For example, they may be unwilling to answer questions and attend group work, even though it is an essential part of many courses. Individuals are not confident about communication resulting in many negative impacts, such as missing opportunities. A student with low self-esteem is also unwilling to ask other questions when they are confused about homework or project. Confusion without clarification can lead to a poor grade. To conclude, Parenting style impacts self-esteem. Self-esteem impact on student’s school performance. Self-esteem as a mediator between parenting style and school performance.

Academic procrastination indicates poor emotional or health conditions that affect the progress of academic performance. Academic procrastination manifests as delayed homework or project and a negative attitude to school. Self-esteem serves as a mediator between parenting style and academic procrastination. According to a previous study, self-esteem appears to mediate in between parenting style and academic self-regulation, which may help decrease academic procrastination and raise academic accomplishment [8]. Authoritative parenting style is positively related with self-esteem. A student with a high level of self-esteem indicates a higher level of self-autonomy. They volunteer to learn without any rules. This type of student usually has a strong learning ability and is very confident about their ability. The study is not a difficult task for them. Autonomy in learning helps to improve academic performance. The other three parenting styles present a lower level of self-esteem than authoritative. A deficiency in self-esteem is increasing academic procrastination. Parents with authoritarian parenting styles always are stringent in the study. They discipline their children with a very severe attitude toward academics. Authoritarian parenting criticizes their children when they make mistakes in academics, such as lower testing grades, which decreases their self-esteem and confidence. Some adolescents are afraid to study because of their parents’ harsh criticism.

Self-regulated learning is a necessary ability for adolescents in academic activities. Self-regulated learning refers to modify or sustain knowledge without explicit instructions. A high level of self-regulated learning enables students to succeed in school performance. Parents play an essential role in children's education programs and different parenting styles impact self-regulated learning distinctively. Self-esteem can be a mediator between positive parenting style and self-regulated learning. Authoritative parenting style can improve self-regulated learning because it provides children with a warm environment for study. Children are more inclined to study in a relaxed environment. Parents' concern and patience can be the key to success in education. It can help children improve their self-regulated learning by improving their interest in their studies. In contrast, a negative environment declines adolescents' willingness to study. Parents who are overly restricted also harm self-regulated learning of children. Adolescents tend to be rebellious during puberty. They
do not prefer rules from others even from their parents. Self-regulation is also impacted by parenting style through self-esteem. In a previous study, Du and his colleagues state self-regulated learning of adolescents is directly predicted by positive parenting style and adolescents can develop their self-regulated ability by building self-esteem [9]. Positive parenting styles such as authoritative parenting style can improve self-esteem. Increasing self-esteem can lead to increasing self-regulated learning. As mentioned previously, students with higher self-esteem are more likely to succeed in school. They have higher confidence in academics and demonstrated more positive attitude accomplishing tasks. A lower level of self-esteem causes a negative attitude and low self-confidence. Thus, self-esteem is a mediator between parenting style and self-regulate learning.

Imposter feeling refers to a self-denial process. People have a lower level of self-worth and tend to deny their success. Individuals hard to believe they are worth it even if they get accepted by other people. Females have a higher chance to experience imposter feelings than males. Self-esteem works as a mediator in the link between parenting style and imposter feelings in female adolescents. Yaffe demonstrates that only overprotection from paternal parenting was substantially connected with the higher imposter sentiments of female young adults via lower self-esteem. In addition, both parents' care was associated with the students' low imposter feelings via high self-esteem [10]. Paternal overprotection usually causes lower self-esteem in female adolescents. Father with overprotection wants to control everything for their children. Because of the high control and protection, female adolescents usually lose the ability of independently thinking. They cannot adopt an independent lifestyle and they doubt their ability for everything. Additionally, the father shows a greater influence than the mother because of the cross-gender relationship. Adequate self-esteem reduces imposter feeling and can facilitate female adolescents know themselves in an optimistic way by noticing their good virtue. The authoritative parenting style also is more beneficial to improve the imposter feelings of females because authoritative parents show more warmth to children. Female adolescents with imposter feelings need more accompany and warmth compared to their peers. Positive and warm parenting styles can increase the self-esteem of females and can improve imposter feelings.

4. Conclusion

This review analyzed the effect of parenting style on self-esteem and other psychological outcomes in adolescents. Only the authoritative parenting style indicated a positive association with self-esteem because parents in this style always demonstrated a positive attitude and emotional support toward their children. The other three parenting styles indicated a negative correlation with self-esteem. Furthermore, many psychological outcomes are impacted by parenting style and self-esteem. The first major part empathized on identity development during adolescence and discussed the relationship between self-esteem and parenting style. Second, lower self-esteem predicts a high level of aggression. The last part presents the mediating role of self-esteem in the relationship between parenting style and learning. A positive parenting style helps adolescents increase self-esteem, which supports young adults to succeed in academics. Plus, it also reduces some mental health problems, such as academic procrastination and imposter feeling. The limitation of recent studies in this area is lacking an analysis of gender differences. Only one article mentioned gender, which examined the relationship between imposter feeling of females and parenting style. The different impacts of parenting style on females and males should be studied more comprehensively in future research. This review can provide some insights for future intervention studies and the design of family education programs at schools and communities.
